6	. . . . .	11
7	. . . . .	11

# 1 Test 1 Stuff (Brief and Important Only)

## 1.1 Units

prefix	base 10 conversion	base 2 conversion
pico	$10^{-12}$	$2^{-40}$
nano	$10^{-9}$	$2^{-30}$
micro	$10^{-6}$	$2^{-20}$
milli	$10^{-3}$	$2^{-10}$
—	$10^0$	$2^0$
kilo	$10^3$	$2^{10}$
mega	$10^6$	$2^{20}$
giga	$10^9$	$2^{30}$
tera	$10^{12}$	$2^{40}$
peta	$10^{15}$	$2^{50}$

- $Hz \implies$  cycles per second
  - $GHz \implies 10^9$  cycles per second
  - etc.

## 1.2 Equations

### 1.2.1 Frequency and Period

- $T = \frac{1}{f}$
- $f = \frac{1}{T}$

### 1.2.2 Wavelength

- $\lambda = vT$
- $f = \frac{v}{\lambda}$ , since  $f = \frac{1}{T} \implies \lambda = \frac{v}{f}$ 
  - for electromagnetic waves in a vacuum,  $v = c$

### 1.2.3 Bandwidth

- $B$  = lowest frequency – highest frequency
  - $Hz$
  - $bps$
  - or any scalar of the above two

### 1.2.4 Delay

- propagation delay =  $\frac{\text{distance}}{\text{speed of light in medium}}$
- transmit delay =  $\frac{\text{packet size}}{\text{bandwidth}}$
- queue delay = buffering and switching delays at nodes
- **total delay** = propagation + transmit + queue
- **RTT** or round-trip-time =  $2 \times \text{delay}$

### 1.2.5 Delay Bandwidth Product

- # of bits =  $B \times D$ 
  - e.g., # of bits =  $10bps \times 10s = 100b$
- this is the number of bits of data that can be sent before the first bit arrives
- we can send  $2(B \times D)$  bits before we receive the first reply bit

### 1.2.6 Shannon Capacity

- maximum theoretical capacity
- $C = B \log_2 \left(1 + \frac{S}{N}\right)$ , where  $\frac{S}{N}$  is the signal/noise ratio
  - high  $\frac{S}{N} \implies$  good capacity
  - low  $\frac{S}{N} \implies$  poor capacity  $\because \log_2(1 + 0) = 0$
- $\frac{S}{N}$  should be in  $Db$

### 1.2.7 Redundancy

- redundancy =  $\frac{n+r}{n}$
- $r$  redundancy bits must cover  $n + r$  bits for errors
  - in other words,  $2^r$  must be able to express  $n + r$  bits
  - this means  $2^r > n + r$
  - or,  $n < 2^r - r$

## 1.3 Error Checking

- VRC
- LRC
- CRC
  - *this is usually used before ARQ*
- checksum

## 2 ARQs

- (A)utomatic (R)epeat Re(Q)uests
- strategy to handle errors detected by the CRC
  - or whatever other detection method
- main types
  - **stop and wait**
  - sliding window
    - **go back N**
    - **selective reject**

### 2.1 Sliding Window

#### 2.1.1 Go Back $N$

- most commonly used sliding window
- sequential frames numbered  $n \bmod N$
- send up to  $N - 1$  frames **before an ACK is received**
- **unbounded sequence numbers** is a hurdle for sliding window in **non-FIFO** channels

#### ACKs and NAKs

- if no error
  - send RR (ACK) for frame[ $n$ ]
- if error
  - send REJ (NAK) for frame[ $n$ ]
- if frame lost, send a NAK
- if no ACK or NAK received before *timeout*, **assume lost**

When Sender Receives a NAK[n]

- resend frame[n] and all frames sent since

When a Sender Receives No ACK or NAK

- go back to the previous ACK and resend all frames sent since

### 2.1.2 Selective Reject

- similar to go back N
- **BUT** we only resend the **lost frame**
  - out of order!
  - receiver needs *sorting logic* to store frames after a NAK
- in general, smaller window size

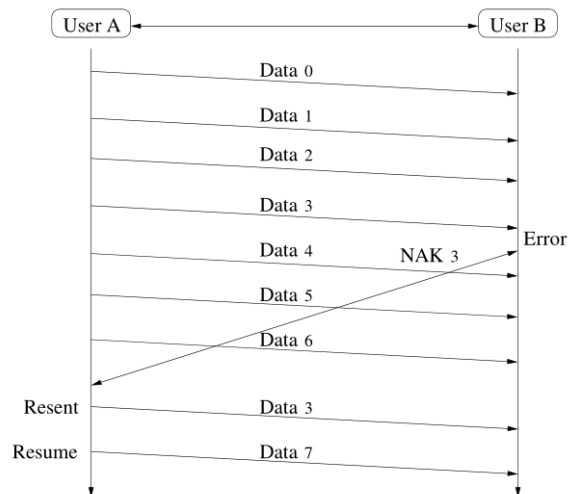

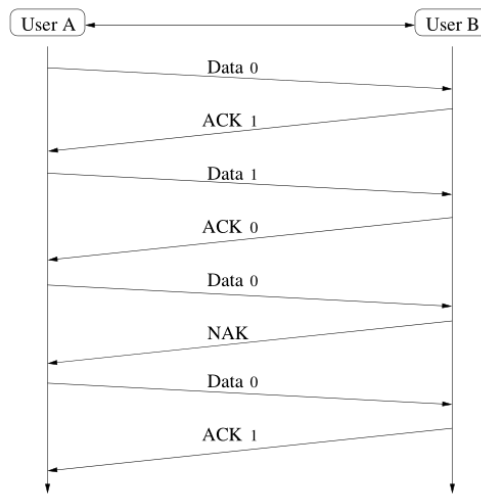

Figure 1: An example of the Selective Reject protocol.

## 2.2 Stop and Wait

- also called an **ABP**
  - *alternating bit protocol*
  - because the label bits alternate between 0 and 1
- you can think of it as sliding “window” with a **window size of 1**
- works only in **FIFO queues**
  - suitable for **data link layer**

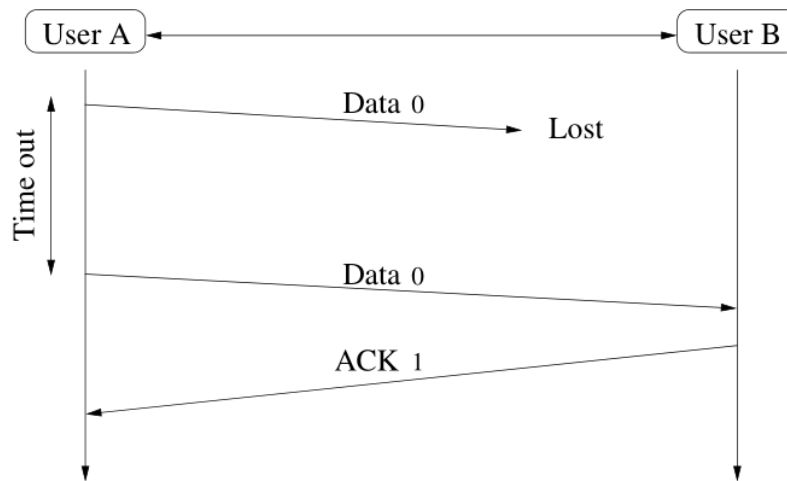

### 2.2.1 Errors in Stop and Wait

- two main types
- **frame errors**
  - damaged frame
- **ACK errors**
  - damaged acknowledgement

**Figure 2:** A diagram of the Stop and Wait ARQ protocol.

### Frame Errors

**Figure 3:** A lost frame error in the Stop and Wait ARQ protocol.

- frame is damaged
  - one or more bits have been altered
- discard the frame
- source waits for ACK
  - if it doesn't receive one, it will resend

### ACK Errors

- frame is received but ACK is damaged
- sender will resend message
- receiver will accept the same message twice
  - so we need to label frames
  - and label ACKs

- use a bit for this
  - $\text{ACK}[b]$  acknowledges frame  $[b + 1 \bmod 2]$
  - says receiver is ready for frame  $[b]$

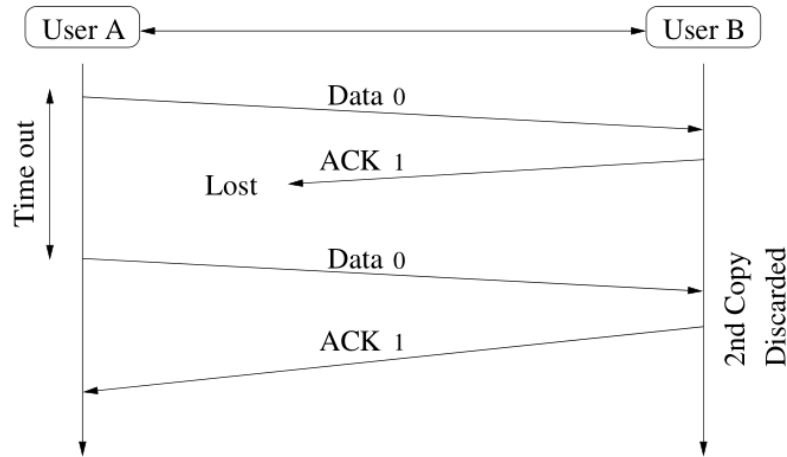

Figure 4: An ACK error in the Stop and Wait ARQ protocol.

### 2.2.2 Correctness

- satisfies:
  - safety
    - algorithm never gives an incorrect result
    - always results in a “corrected” error
  - liveness
    - never enters a deadlock condition

## 3 Multiaccess

### 3.1 LANs

- two types
  - **switched**
    - lines, multiplexes, switches
    - hierarchical addressing scheme
    - routing tables
  - **broadcast**
    - no routing
    - flat addressing scheme
    - (M)edium (A)ccess (C)ontrol to coordinate transmissions
    - **preferred over switched** due to **simplicity**

### 3.2 The Problem with Shared Channels

- in *point-to-point* networks we have signal as a function of one transmitted signal
- in *shared* networks, we may have **more than one** transmission contributing to a signal

### **3.3 MAC Protocol**

### **3.4 Uncoordinated Access Control**

### **3.5 Ethernet**

### **3.6 Coordinated Access**

#### **3.6.1 Tree Algorithm**

#### **3.6.2 Binary Countdown**

#### **3.6.3 Bitmap**

## **4 Wireless**

### **4.1 Cellular**

### **4.2 Ad Hoc**

#### **4.2.1 UDG**

#### **4.2.2 Compass Routing**

#### **4.2.3 Face Routing**

### **4.3 Bluetooth**

## **5 GPS**

### **5.1 Three Techniques**

### **5.2 Satellites**

## **6 Routing**

### **6.1 Distance Vector (RIP)**

### **6.2 Link State Protocol (LSP)**

### **6.3 MSTs**

### **6.4 Dijkstra**

## **7 IP**

### **7.1 IPv4**

#### **7.1.1 Classes of Address**

#### **7.1.2 Subnets**

#### **7.1.3 Subnet Masks**

### **7.2 IPv6**

### **7.3 DHCP**

### **7.4 ARP**

#### **7.4.1 RARP**

## **8 TCP**

### **8.1 How it Works (Sliding Window)**

## 9 Sample Test

### 1

A system has an  $n$ -layer protocol hierarchy. Applications generate messages of length  $M$  Bytes. At each level of the layers, an  $h$ -Byte header is added.

#### 1.1

[3 pts] What fraction of the network bandwidth is filled with headers? (Give the formula.)

$$\text{overhead} = \frac{nh}{nh + M}$$

#### 1.2

[3 pts] Now assume  $M = 20h$ . What should the max number  $n$  of layers be so that the fraction in previous Question 1 does not exceed 10 % of the total?

$$\begin{aligned} \text{overhead} &= \frac{nh}{nh + M} \\ 10\% &\geq \frac{nh}{nh + 20h} \\ \frac{1}{10} &\geq \frac{n}{n + 20} \\ (n + 20)\frac{1}{10} &\geq n \\ (n + 20)\frac{1}{10} &\geq n \\ \frac{n}{10} + 2 &\geq n \\ n + 20 &\geq 10n \\ 20 &\geq 9n \\ n &\leq \frac{20}{9} \end{aligned}$$

#### 1.3

Two CDMA users are assigned the 9-bit vectors  $A = 110011011, B = 100101111$ , respectively. Are they orthogonal? (Prove or disprove!) **Hint:** Recall  $0 \rightarrow -1$  and  $1 \rightarrow +1$ .

Take inner product of vectors in mod 2.

$$\begin{aligned} \langle \vec{A}, \vec{B} \rangle \mod 2 &= 1 + 0 + 0 + 0 + 1 + 0 + 0 + 1 + 1 \mod 2 \\ &= 0 \end{aligned} \quad \Longleftrightarrow \text{orthogonal}$$

## 2

You are observing a ship from two base stations  $A, B$ . Assume that at this time of observation  $\alpha = \pi/3, \beta = \pi/4$  and  $d = 1000 \text{ m}$ .

Derive a formula for the unknown distance  $x$  (You are not required to evaluate the trigonometric functions of  $\pi/3$  and  $\pi/4$ ).
